WEBER COUNTY, UTAH 84401
STORM WATER STUDY**
Project No. 21N724
6-9-2021
Revised 8-4-2021
Revised 8-24-2021

General Site Information:

The proposed residential site is located approximately at 900 South 3500 West. The site is situated about 1,000 ft to the west of the Weber River in Weber County, Utah. Construction will consist of a 97-lot residential subdivision prepared for development along with site grading, sidewalks, curb and gutter, underground utilities, and landscaped areas when completed.

Storm water from the site will be collected in inlet boxes and catch basins and will continue via storm drain to the northwest and northeast corners of the study area. Storm water will be detained in a detention pond located at each of those corners of the site. The site is divided into two phases with 48 lots on the west side (Phase 1) and 49 lots on the east side (Phase 2). Each phase is allowed a unit-release of 0.1 cfs per acre for the 100-yr storm. Phase 1 discharges into an existing ditch which meanders northerly, westerly, and southerly before combining with the Weber River. Phase 2 discharges into an existing ditch near the east side of the site, which flows northerly and easterly before combining with the Weber River. The attached figure shows the project site and location of the storm water outfall. Detention calculations have been provided for the site. (See attached figure and calculations).

The study area is broken up into 6 drainage areas (labeled A-1 through A-6). A runoff coefficient of 0.15 is used for natural ground and landscaped areas. A runoff coefficient of 0.90 is used for asphalt, concrete, buildings, and other hard surfaced areas. An average runoff coefficient was calculated for each of the drainage areas. The calculated coefficients are 0.52, 0.53, 0.46, 0.50, 0.51 and 0.50 for A-1 through A-6 respectively. This yields a coefficient of 0.50 for the overall study area.

Times of concentration are calculated using the FAA method assuming flow resistance coefficients of K=0.35 for landscape and K=0.91 for hardscape for each of the areas. The times of concentration are about 20, 19, 22, 16, 20 and 24 respectively for areas A-1 through A-6. These times are based on the hydraulically longest drainage path inside each respective drainage area over grass or other vegetation, asphalt, concrete, and/or through a pipeline as applicable. Times calculated to be less than 5 minutes are rounded to 5 minutes (as applicable) when using this method. Rainfall Intensities were taken from NOAA Atlas 14 for pipe sizing and detention requirements. The values obtained were interpolated as necessary. A copy of these data is attached.

Data showing area information, runoff coefficient, time of concentration, peak flows, and detention storage requirements for the site are also provided and can be found in the attached calculations.

Design Requirements:

The design storms and allowable stormwater release rate were found at the weber county website and verified with the County Engineer on 5/28/2021. For storm drain piping, the requirement is listed as the “10-year frequency storm” for multiple initial collection points and conveyance (pipes) and “0.1 cfs/acre per 100-year frequency rainfall event” for major collection (detention pond) of multiple initial systems.

Pipe Sizes:

Storm water pipes in the project are proposed to be concrete pipe (CP), and/or reinforced concrete pipe (RCP). All pipes in the project are sloped to provide the design capacity while maintaining a minimum scour speed of at least 2 feet per second when the pipes are flowing at least half full. The pipes and inlet boxes have enough capacity to convey the 10-year storm without surcharging.

Orifice Plate:

An orifice plate will be used in the detention pond serving each phase to control the rate that storm water flows from the project. They will be located on the downstream face of the outlet structures labeled as nodes 27 and 50 (See attached figure). The orifice openings are given designations of nodes 100 and 101 for convenience in modeling the reduced flow through the restriction. The orifice plate openings will be sized to allow a release rate of no more than 0.1 cfs/ac. The orifice plates will allow small flows to pass through without detention. As the rate of storm water into the pipes and detention facilities increase, the orifice plate will restrict the flow. The maximum flow through the plate will occur when the detention basins reach their maximum design depth. A detail for an orifice plate can be found in the construction documents for this project.

Required Detention:

For Phase 1, the required detention storage for the 100-year storm with a release rate of 0.1 cfs/acre is 51,041 cf. There is capacity provided in the pond at the northwest corner of the subdivision to meet or exceed this requirement. The required detention for the design storm and allowable release is 41,455 cubic feet for Phase 2. Storage capacity will be designed/provided to meet this requirement when phase 2 is developed. In the event either detention facility experiences a storm larger than the design storm water will then spill out through an overflow structure and into the afore-mentioned existing ditches and proceed downstream.

¹ Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Please refer to NOAA Atlas 14 document for more information.
